Field type mismatches in error in Drupal migration, how to fix it?

In Drupal migrations, **“field type mismatch” errors** usually mean that the **destination field expects a different data type or structure** than what the migration is providing.

Below is a practical way to **diagnose and fix** them.

---

1. Understand what the error means

A typical error looks like:

> *Field field_example expects type integer, but got string*

This means one of these is wrong:

- The **destination field type** (Drupal field configuration)
- The **source value format**
- The **process pipeline** converting the value

---

2. Check the destination field definition (most common issue)

Go to:

/admin/structure/types/manage/[content-type]/fields

Verify:

- Field type (text, integer, entity reference, date, boolean, etc.)
- Cardinality (single vs multiple)
- Storage type (e.g. `integer` vs `string`)

Example mismatch

Destination field	Source value
Integer field	`"123"` (string)
Entity reference	Node title instead of ID
Date field	Non-ISO date

---

3. Fix using process plugins (best practice)

Convert string → integer

```
process:
  field_age:
    plugin: callback
    callable: intval
    source: age
```

Or:

```
process:
  field_age:
    plugin: default_value
```

```
    default_value: 0
```

---

4. Entity reference mismatches (VERY common)

❌ **Wrong**

```
field_author: author_name
```

✅ **Correct (lookup by ID)**

```
process:
  field_author:
    plugin: migration_lookup
    migration: users
    source: author_id
```

If matching by name:

```
process:
  field_author:
    plugin: entity_lookup
    entity_type: user
    value_key: name
    source: author_name
```

---

5. Date field mismatches

Drupal date fields expect **ISO 8601**.

Fix with `format_date`

```
process:
  field_event_date:
    plugin: format_date
    from_format: 'm/d/Y'
    to_format: 'Y-m-d\TH:i:s'
    source: event_date
```

---

6. Multi-value field mismatch

If the destination field allows multiple values but source is a string:

```
process:
  field_tags:
    plugin: explode
    delimiter: ','
    source: tags
```

---

7. Debug the actual value being imported

Add this temporarily:

```
process:
```

```
  debug_field:
    plugin: callback
    callable: var_dump
    source: field_name
```

Or run:

```
drush migrate:messages migration_id
```

This shows **exact values causing failure**.

---

8. Clear field schema cache after changes

After changing field types:

```
drush cr
```

If field storage changed:

```
drush entity:updates
```

---

9. Quick checklist

✔ Destination field type matches source
✔ Correct process plugin used
✔ Entity references use IDs, not labels
✔ Dates formatted correctly
✔ Multi-value fields handled properly

---

10. If you want targeted help

If you paste:

- The **error message**
- The **field definition**
- The **migration YAML**

I can pinpoint the fix immediately.

Common error message in Drupal Migration

Below are the **most common error messages** you'll see when migrating **Drupal 7 → Drupal 10**, what they mean, and **how to fix them**. These come up constantly in real-world migrations.

---

1. `Field type mismatch` / `The field type does not match`

Message examples

- *Field field_image expects type entity_reference but got string*
- *The field storage definition does not match*

Cause • Field type changed between D7 and D10 • Source value doesn't match destination field schema	**Fix** • Check destination field type • Add correct process plugin:	plugin: migration_lookup or plugin: entity_lookup • Clear caches: drush cr drush entity:updates

2. `No process plugin found for…`

Message Plugin (xyz) not found **Cause** • Plugin name typo • Plugin removed or renamed in D10 • Contrib module missing	**Fix** • Verify plugin exists: drush php:eval "print_r(\Drupal::service('plugin.manager.migrate.process')->getDefinitions());" • Enable required module • Use core plugin alternative

3. `Missing destination plugin`

Message

Missing destination plugin for migration

Cause • Destination plugin not defined • Incorrect destination ID	**Fix** destination: plugin: 'entity:node'

4. `Migration failed with source plugin exception`

Message

SQLSTATE[42S02]: Base table or view not found

Cause • Wrong source database • Missing D7 tables • Incorrect database key	**Fix** • Verify `settings.php` database entry • Test connection: drush sqlq "SHOW TABLES;"

5. `Entity not found` / `Unable to load entity`

Message Unable to load the referenced entity **Cause** ● Entity reference points to non-existent entity ● Lookup migration hasn't run yet	**Fix** ● Run migrations in order: drush migrate:import users drush migrate:import nodes ● Add dependency: migration_dependencies: required: - users

6. `Illegal choice` / `Invalid value`

Message

Illegal choice for field field_status

Cause ● List field value not in allowed values ● D7 and D10 options don't match	**Fix** process: field_status: plugin: static_map map: old_value: new_value

7. `DateTime::__construct(): Failed to parse time string`

Cause ● Invalid or non-ISO date format	**Fix** process: field_date: plugin: format_date from_format: 'm/d/Y' to_format: 'Y-m-d\TH:i:s'

8. `Undefined index` / `Notice: Undefined property`

Cause ● Field exists in D10 but not in D7 data ● Wrong source field name	**Fix** process:

	field_example: plugin: skip_on_empty source: missing_field

9. `SQLSTATE[23000]: Integrity constraint violation`

Cause	Fix
● Duplicate values in unique fields ● Re-running migrations without rollback	drush migrate:rollback migration_id drush migrate:import migration_id or: ids: nid: type: integer

10. `You are not allowed to create this entity`

Cause	Fix
● User roles/permissions not migrated ● Anonymous user running migration	● Run migrations as admin ● Migrate users and roles first

11. `The bundle does not exist`

Cause	Fix
● Content type / vocabulary not created ● Config not imported	drush cim or: drush migrate:import d7_node_type

12. `File not found` / `Unable to copy file`

Cause	Fix
● `file_public_path` wrong ● Missing files directory	$settings['file_public_path'] = 'sites/default/files'; Ensure files exist and permissions are correct.

Migration order that prevents most errors

system	taxonomy_vocabulary	field

users user_roles	taxonomy_term node_type	file node

Debugging commands you should always use

drush migrate:status

drush migrate:messages migration_id

drush migrate:rollback migration_id

drush migrate:import migration_id -vvv

Give a **safe migration order** for your site

Below is a **safe, battle-tested migration order** for **Drupal 7 → Drupal 10** that avoids most fatal errors (missing bundles, entity references, files, users, etc.).

This order assumes you are using **core migrate + migrate_drupal** (and optionally migrate_plus).

✅ Phase 0: Preparation (DO NOT SKIP)

drush cr drush cim

Make sure:

- All content types, vocabularies, and fields exist (or will be created by migration)
- `migrate_drupal` is enabled
- Source DB is correctly configured

✅ Phase 1: System & Configuration

These migrations create **dependencies** needed by everything else.

drush migrate:import d7_system

drush migrate:import d7_filter_format

drush migrate:import d7_user_role

Why:

- Text formats must exist
- Roles must exist before users

✅ Phase 2: Users

drush migrate:import d7_user

Why:

- Nodes, comments, files, media reference users
- Prevents “Unable to load user entity” errors

✅ Phase 3: Taxonomy (Vocabulary → Terms)

drush migrate:import d7_taxonomy_vocabulary

drush migrate:import d7_taxonomy_term

Why:

- Fields often reference taxonomy terms
- Prevents “Entity not found (taxonomy_term)” errors

✅ Phase 4: Content Structure (Bundles & Fields)

drush migrate:import d7_node_type

drush migrate:import d7_field

drush migrate:import d7_field_instance

Why:

- Content types must exist before content
- Fields must exist before field data

✅ Phase 5: Files & Media

drush migrate:import d7_file

Optional (if using Media module):

drush migrate:import d7_media

Why:

- Nodes reference files/images
- Prevents file ID lookup failures

✅ Phase 6: Content (Nodes)

drush migrate:import d7_node

For large sites:

drush migrate:import d7_node --limit=50

Why:

- All dependencies must exist first
- Prevents entity reference and bundle errors

✅ Phase 7: Comments

drush migrate:import d7_comment

Why:

- Comments depend on nodes and users

✅ Phase 8: Menus & Menu Links

drush migrate:import d7_menu

drush migrate:import d7_menu_links

✅ Phase 9: Blocks

drush migrate:import d7_block

✅ Phase 10: URLs & Redirects

drush migrate:import d7_url_alias

Optional:

drush migrate:import d7_path_redirect

✅ Phase 11: Final Cleanup

drush cr

drush entity:updates

drush migrate:status

🚨 Common mistakes this order avoids

Error	Prevented by
Bundle does not exist	Node types before nodes
Entity not found	Users, taxonomy first
File missing	Files before nodes
Field storage mismatch	Field migrations before content
Invalid text format	Filter formats early

🧠 Pro tip (best practice)

Instead of running individually:

drush migrate:import --group=drupal7

Or:

drush migrate:import --tag=Drupal 7

Drupal will respect dependencies automatically.

🧪 Debugging safety commands

drush migrate:messages d7_node

drush migrate:rollback d7_node

drush migrate:import d7_node -vvv

Below is a **step-by-step migration guide**, with **detailed explanations for each step**, reflecting current best practices for Drupal 10 and Drupal 11.

High-Level Overview

Drupal 7 → Drupal 10/11 migration involves:

1. Assessing the existing site
2. Planning the new architecture
3. Preparing the Drupal 7 source
4. Setting up Drupal 10/11
5. Migrating configuration
6. Migrating content
7. Migrating users
8. Rebuilding custom functionality
9. Theming rebuild
10. Testing & validation
11. Go-live & post-migration cleanup

---

1. Audit and Assess the Drupal 7 Site

Purpose

Understand **what exists**, **what can be migrated**, and **what must be rebuilt**.

What to Inventory

- **Core version** (e.g., 7.98)
- **Contributed modules**
- **Custom modules**
- **Content types**
- **Fields**
- **Taxonomies**
- **Users & roles**
- **Views**
- **Panels / Context**
- **Theme**
- **Custom database tables**
- **Third-party integrations**

Tools

- **Upgrade Status module (Drupal 7 version)**
- **Drupal Module Upgrader**
- Spreadsheet or documentation tool

Key Decisions

- Which modules:
  - Have Drupal 10/11 equivalents?
  - Are obsolete and can be dropped?
  - Must be replaced with core functionality?

📌 **Outcome:** A clear migration scope and risk assessment.

Decide What to Migrate

Item	Approach
Content	Automated migration
Users	Automated migration
Taxonomy	Automated migration
Files	Automated migration
Views	Rebuild
Panels	Rebuild using Layout Builder
Custom Modules	Rewrite
Theme	Full rebuild

📌 **Important:** Drupal 7 configuration **cannot** be migrated automatically.

Drupal migration cheat-sheet

Here's a **concise but complete Drupal migration cheat-sheet** (focused on **Drupal 7 → Drupal 10**). You can keep this handy while migrating or debugging.

🧾 Drupal Migration Cheat-Sheet (D7 → D10)

1️⃣ Required modules

```
drush en migrate migrate_drupal migrate_plus migrate_tools -y
```

2️⃣ Source database setup (`settings.php`)

```
$databases['migrate']['default'] = [
  'database' => 'drupal7db',
  'username' => 'user',
  'password' => 'pass',
  'host' => 'localhost',
  'driver' => 'mysql',
];
```

3️⃣ Safe migration order (summary)

1. system 2. filter_format 3. user_role 4. user 5. taxonomy_vocabulary 6. taxonomy_term	7. node_type 8. field 9. field_instance 10. file 11. node	12. comment 13. menu 14. menu_links 15. block 16. url_alias

Best shortcut:

drush migrate:import --tag="Drupal 7"

4️⃣ Most-used Drush commands

drush migrate:status

drush migrate:import migration_id

drush migrate:rollback migration_id

drush migrate:messages migration_id

drush migrate:import migration_id -vvv

5️⃣ Common process plugins (with examples)

🔁 `migration_lookup`

(Entity reference)

field_author:

  plugin: migration_lookup

  migration: d7_user

  source: uid

🔍 `entity_lookup`

(Lookup by label)

field_term:

  plugin: entity_lookup

  entity_type: taxonomy_term

  value_key: name

  source: term_name

🗂️ `static_map`

(Fix illegal choice errors)

```
field_status:
  plugin: static_map
  map:
    old_value: new_value
```

📅 `format_date`

```
field_date:
  plugin: format_date
  from_format: 'm/d/Y'
  to_format: 'Y-m-d\TH:i:s'
```

🧩 `explode`

(Multi-value fields)

```
field_tags:
  plugin: explode
  delimiter: ','
```

⛔ `skip_on_empty`

```
plugin: skip_on_empty
method: process
source: field_optional
```

🔢 **Convert string → integer**

```
plugin: callback
callable: intval
```

6️⃣ Common error messages → Fix

Error	Fix
Field type mismatch	Fix destination field or process plugin
Entity not found	Run referenced migration first
Illegal choice	Use static_map
Invalid date	Use format_date
Bundle does not exist	Import node type first
SQLSTATE table not found	Check source DB
Duplicate key	Rollback before re-import

7️⃣ Migration dependencies

```
migration_dependencies:
  required:
    - d7_user
    - d7_taxonomy_term
```

8️⃣ Rollback safely

```
drush migrate:rollback d7_node
drush migrate:import d7_node
```

⚠️ Roll back in **reverse order**

9️⃣ Debugging tips

```
drush migrate:messages migration_id
drush migrate:import migration_id -vvv
```

Temporary debug:

```
plugin: callback
callable: var_dump
```

🔟 Field type mapping (D7 → D10)

Drupal 7	Drupal 10
File field	Media / File entity
Term reference	Entity reference
Number (integer)	Integer
Text	Text / Text long
Image	Media image

🧠 Best practices

✔ Migrate **users first**
✔ Migrate **structure before content**
✔ Always rollback before re-running
✔ Use `--limit` for large sites
✔ Keep YAML changes versioned

List of Drupal Migration Plugins and their solutions

Here's a **comprehensive overview of the major Drupal Migrate plugins** and typical **solutions/workarounds** you'll encounter when using them. Drupal's migrate system is built on *three plugin types* — **Source**, **Process**, and **Destination** — plus *migration definitions* themselves. (Drupal.org)

✅ 1. Migration Plugins (Definitions)

A **migration plugin** is a YAML file that defines one ETL (extract-transform-load) job:

- **id / label** — unique ID and human label.
- **source** — which *source plugin* to use.
- **process** — mapping values with *process plugins*.
- **destination** — where data ends up (*destination plugins*).
- **migration_dependencies** — other migrations that must run first. (Drupal.org)

Solution Tips

- Always set `migration_dependencies` when one migration depends on another (e.g., author before articles).
- Use `migration_groups` (via **Migrate Plus**) to organize related migrations. (Drupal.org)

✅ 2. Source Plugins

Source plugins fetch rows from a data source. Core and contrib modules provide many:

Plugin	Provided By	What It Does	Common Solutions
`d6_node`, `d7_node` etc.	**Core (migrate_drupal)**	Pulls content from old Drupal6/7	Ensure `migrate_drupal` is enabled for Drupal-to-Drupal upgrades. (Drupal.org)
`csv`	**Migrate Source CSV (contrib)**	Read CSV files	Install and configure properly with path & delimiter. (Drupal.org)
`url`, `simple_xml`, `json`	**Migrate Plus**	Fetch JSON/XML via HTTP	Make sure `data_fetcher_plugin` and `data_parser_plugin` are set. (Drupal.org)
`table`	**Migrate Plus**	SQL table source	Use correct DB key in settings.php with multiple DBs. (Drupal.org)
`embedded_data`	**Core / Examples**	Hard-coded demo data	Good for testing migrations. (Drupal.org)

Common Issues & Solutions (Source)

- **Data not found**: Check your `source:` config, aliases for DB tables, and ensure settings.php includes the second DB connection.
- **IDs too long**: Source IDs longer than field limits may error — set `max_length` for `id` fields. (Drupal.org)

✅ 3. Process Plugins

Process plugins transform or map source values to destination fields. Core Drupal provides many, and **Migrate Plus** adds useful extra ones. (Drupal.org)

🔹 **Core Process Plugins**

Plugin	What It Does
`get`	Default: get source field value
`concat`	Join strings
`default_value`	Use a fallback value
`migration_lookup`	Look up a value from a previous migration
`make_unique_entity_field`	Ensure unique values
`explode`, `sub_process`	Split arrays or run nested pipelines
`urlencode`, `format_date`	Encode/convert values
`skip_on_empty`	Skip row if empty
`entity_exists`	Check destination entity before saving

🔹 **Contributed/Enhanced Process Plugins (Migrate Plus / Tools)**

Plugin	What It Does
`entity_lookup`	Query existing entities (not from migrations)
`entity_generate`	Lookup or *create* entities when missing
`file_blob`	Create files from blob data
`merge`	Combine multiple arrays
`str_replace`, `dom`	Transform HTML/XML strings

Solutions & Tips (Process)

- **Referencing existing users/taxonomy**: Use `entity_lookup` to find real Drupal entities, or `entity_generate` to auto-create missing ones. (Understand Drupal)
- **Inter-migration relationships**: Use `migration_lookup` to match content migrated earlier (e.g., author → article). But it only works between migrations, not arbitrary Drupal entities. (Understand Drupal)
- **Error "plugin does not exist"**: Check spelling and module enabling — contrib process plugins often come from **migrate_plus** / **migrate_tools**. Enable those to fix missing plugin errors.
- **Multiple matches not returned**: `migration_lookup` traditionally returns one value — use array helpers or write custom plugin if multiple linked values are needed. (Drupal.org)

✅ 4. Destination Plugins

Destination plugins write data into Drupal's storage.

Plugin	What It Targets
entity:node	Create nodes
entity:taxonomy_term	Taxonomy terms

entity:user	Users
entity:file	File entities
entity:media	Media entities
entity:commerce_product	Commerce products

Solutions & Best Practices

- Ensure proper bundle configuration with destination (`default_bundle`).
- Media migration typically requires multiple stages (file first, then media reference). Custom migrations or plugins like **migrate_files** can help.

🧠 Debugging & Common Migration Problems

❗ Missing or Invalid Plugin Errors

- Often caused by enablement issues (missing module).
- Check plugin ID spelling and clear cache.
- Verify the module that provides the plugin (e.g., **migrate_plus**).
  Solution: `composer require drupal/migrate_plus` & `drush en migrate_plus migrate_tools`.

❗ Relationships Not Preserved

If relationships (like many-to-many) don't map correctly:

Solution: Use `migration_lookup` inside a `sub_process` to map related sets.
Example pattern:

```
field_authors:
  plugin: sub_process
  source: id
  process:
    target_id:
      plugin: migration_lookup
      source: author_id
      migration: authors_migration
```

This nests a lookup inside each loop. (Reddit)

❗ Updating Existing Content Instead of Creating New

Default behavior is to create new entities.
Solution: Use unique identifiers (UUIDs) in source and enable update behavior with `track_changes` or by specifying `uuid:` in YAML. Also migrate with Drush flags like `--update`. (Drupal.org)

📌 Summary Cheat Sheet

Plugin Type | Purpose | Examples

- **Source** — Fetch data
  - Core: `d7_node`, `embedded_data`
  - Contrib: `csv`, `url/json` (Migrate Plus)
- **Process** — Transform data
  - Core: `concat`, `migration_lookup`, `default_value`
  - Contrib: `entity_lookup`, `entity_generate`, `file_blob`
- **Destination** — Save data
  - `entity:node`, `entity:user`, `entity:media`, etc.

If you want, I can also generate **example YAML** snippets for each plugin type (e.g., migrating CSV to nodes with taxonomy and entity references) to help you build migrations faster.

Create a **full working example with multiple content types, users, files, and taxonomy migration** ready-to-run for Drupal 7 → Drupal 10/11. It would include **custom source plugins** for serialized fields and entity references.

Perfect! Let's build a **ready-to-run D7 Entity Reference source plugin** so your migrated nodes, taxonomy terms, and files keep their relationships intact. This is critical for content like Articles referencing Tags or Media files.

1️⃣ Plugin: D7EntityReference.php

Create this file in:

custom_migration/src/Plugin/migrate/source/D7EntityReference.php

Code:

```
<?php

namespace Drupal\custom_migration\Plugin\migrate\source;

use Drupal\migrate_drupal\Plugin\migrate\source\Drupal7Node;

use Drupal\migrate\Row;

/**
 * Source plugin for D7 nodes with entity references.
 *
 * @MigrateSource(
 *   id = "d7_entity_reference_node"
 * )
 */
class D7EntityReference extends Drupal7Node {
  /**
   * Prepare each row for migration.
```

```
 *
 * @param \Drupal\migrate\Row $row
 *   The row object.
 *
 * @return bool
 *   TRUE if row is valid.
 */
public function prepareRow(Row $row) {
  // Handle taxonomy term references
  $term_refs = $row->getSourceProperty('field_tags');
  if ($term_refs && is_array($term_refs)) {
    $mapped_terms = [];
    foreach ($term_refs as $term_ref) {
      if (isset($term_ref['tid'])) {
        $mapped_terms[] = $term_ref['tid'];
      }
    }
    $row->setSourceProperty('field_tags', $mapped_terms);
  }
  // Handle file references (images, attachments)
  $file_refs = $row->getSourceProperty('field_image');
  if ($file_refs && is_array($file_refs)) {
    $mapped_files = [];
    foreach ($file_refs as $file_ref) {
      if (isset($file_ref['fid'])) {
        $mapped_files[] = $file_ref['fid'];
      }
    }
    $row->setSourceProperty('field_image', $mapped_files);
  }
  return parent::prepareRow($row);
}
}
```

2️⃣ Example YAML Migration Using This Plugin

`migrations/articles_with_refs.yml`:

```yaml
id: migrate_d7_articles_refs
label: 'Migrate D7 Articles with Entity References'
migration_group: custom_migration
source:
  plugin: d7_entity_reference_node
  node_type: article
process:
  title: title
  body: body/value
  created: created
  changed: changed
  uid: uid
  field_tags:
    plugin: migration_lookup
    migration: migrate_d7_tags
    source: field_tags
  field_image:
    plugin: migration_lookup
    migration: migrate_d7_files
    source: field_image
destination:
  plugin: 'entity:node'
  default_bundle: article
migration_dependencies:
  required:
    - migrate_d7_tags
    - migrate_d7_files
```

Explanation:

- `plugin: migration_lookup` maps the source IDs (tids, fids) to the new migrated IDs in Drupal 10/11.
- `migration_dependencies` ensures taxonomy terms and files are migrated **before** this migration.

3️⃣ Migration Order

To avoid broken references, run migrations in this order:

1. Users (`migrate_d7_users`)
2. Taxonomy (`migrate_d7_tags`)
3. Files (`migrate_d7_files`)
4. Content with references (`migrate_d7_articles_refs`, `migrate_d7_pages`)

4️⃣ Running and Debugging

Run migration

drush migrate:import migrate_d7_articles_refs

Check messages for missing references

drush migrate:messages migrate_d7_articles_refs

Rollback if needed

drush migrate:rollback migrate_d7_articles_refs

✅ Key Notes

- Works for **node → node references, taxonomy term references, and file references**.
- Can be extended to **media entities** or other custom entity types.
- Use `prepareRow()` for **any additional field transformation** (serialized fields, JSON, etc.).
- Always test in **staging** before production migration.

How to migrate Image Fields from D7 to D11

Migrating **image fields** from **Drupal 7 to Drupal 11** involves more than just migrating the node — you have to migrate the **file entities**, preserve their **file IDs (FIDs)**, and ensure the **image fields** on nodes point to the correct files in Drupal 11. Here's a clear, step-by-step guide:

1️⃣ Step 1: Prepare the Drupal 11 Environment

1. Install a clean **Drupal 11** site.
2. Enable the necessary migration modules:
   - `Migrate`
   - `Migrate Drupal`
   - `Migrate Plus`
   - `Migrate Tools`

3. Ensure that the **content types** in Drupal 11 match your Drupal 7 site, with the **image fields** created using the same machine name.

2️⃣ Step 2: Migrate Files First

Image fields in Drupal nodes reference **file entities**, so you must migrate the files before the nodes.

Example YAML: `migrations/files.yml`

```
id: migrate_d7_files
label: 'Migrate D7 Files'
migration_group: custom_migration
source:
  plugin: d7_file
process:
  fid: fid
  filename: filename
  uri: uri
  filemime: filemime
  status: status
  uid: uid
destination:
  plugin: entity:file
migration_dependencies: {}
```

- **Important**: The `uri` field must be migrated correctly. Drupal 7 uses `public://` or `sites/default/files/`; Drupal 11 also uses `public://`.
- If your files are stored locally, ensure the **files are copied** from Drupal 7 to Drupal 11's `sites/default/files` directory.

3️⃣ Step 3: Migrate Nodes With Image Fields

Once files are migrated, you can migrate nodes.

Example YAML: `migrations/articles_with_images.yml`

```
id: migrate_d7_articles_images
label: 'Migrate D7 Articles with Images'
migration_group: custom_migration
source:
  plugin: d7_node
  node_type: article
process:
  title: title
  body: body/value
  created: created
  changed: changed
  uid: uid
  field_image:
    plugin: migration_lookup
    migration: migrate_d7_files
    source: field_image
destination:
  plugin: 'entity:node'
  default_bundle: article
```

```
migration_dependencies:
  required:
    - migrate_d7_files
```

Key Points:

- Use the **`migration_lookup` plugin** to map the old Drupal 7 file IDs (`fid`) to the new Drupal 11 file entities.
- `migration_dependencies` ensures files are imported **before** nodes, so the references are valid.

4️⃣ Step 4: Custom Handling for Multi-Value Image Fields

If your image field allows multiple images, you need to ensure the migration handles arrays:

```
field_images:
  plugin: iterator
  source: field_images
  process:
    target_id:
      plugin: migration_lookup
      migration: migrate_d7_files
      source: fid
    alt: alt
    title: title
```

- `iterator` loops through each image in a multi-value field.
- You can map additional properties like `alt` and `title`.

5️⃣ Step 5: Copy File Contents

Drupal migration **does not automatically copy files**. You need to copy them manually or use a script:

```
rsync -av sites/default/files/ /path/to/drupal11/sites/default/files/
```

- Ensure the **file permissions** allow Drupal 11 to read the files.

6️⃣ Step 6: Run Migration

Using Drush:

```
# Migrate files first
drush migrate:import migrate_d7_files

# Migrate nodes with images
drush migrate:import migrate_d7_articles_images

# Check migration messages
drush migrate:messages migrate_d7_articles_images
```

7️⃣ Step 7: Verify Images

- Check that **nodes display the correct images**.
- Confirm **alt text, title, and file references** are correct.
- Test **multi-value image fields** if applicable.

✅ Tips

1. Always migrate **files before nodes**.
2. Use `migration_lookup` for all entity references (files, taxonomy terms, users).
3. Copy files **before migration** to match their URIs.
4. Test in **staging**, not directly in production.

If you want, I can create a **full ready-to-run example migration YAML + custom plugin** specifically for **Drupal 7 articles with multi-image fields**, including `alt`, `title`, and FID mapping, so it's fully production-ready for Drupal 11.

Do you want me to do that?

yes

Perfect! Let's create a **full ready-to-run Drupal 7 → Drupal 11 image migration** example that handles:

- Single and multi-value image fields
- `fid` mapping to new Drupal 11 files
- `alt` and `title` attributes
- Node migration referencing the images

1️⃣ Module Structure

```
custom_migration/
├── custom_migration.info.yml
├── custom_migration.migrations.yml
├── migrations/
│   ├── files.yml
│   └── articles_images.yml
└── src/
    └── Plugin/migrate/source/
        └── D7SerializedNode.php
```

2️⃣ Module Info File

`custom_migration.info.yml`:

```yml
name: Custom Migration
type: module
description: 'Custom migrations from Drupal 7 to Drupal 11, including images.'
core_version_requirement: ^11
dependencies:
  - drupal:migrate_plus
  - drupal:migrate_tools
package: Migration
```

3 Migration Group YAML

`custom_migration.migrations.yml`:

```
id: custom_migration
label: 'Custom Migration Group'
description: 'Group of migrations including files and articles with images.'
```

---

4 Files Migration

`migrations/files.yml`:

```
id: migrate_d7_files
label: 'Migrate D7 Files'
migration_group: custom_migration
source:
  plugin: d7_file
process:
  fid: fid
  filename: filename
  uri: uri
  filemime: filemime
  status: status
  uid: uid
destination:
  plugin: entity:file
migration_dependencies: {}
```

> **Note:** Copy files manually before migration:

```
rsync -av sites/default/files/ /path/to/drupal11/sites/default/files/
```

---

5 Articles with Image Fields Migration

`migrations/articles_images.yml`:

```
id: migrate_d7_articles_images
label: 'Migrate D7 Articles with Images'
migration_group: custom_migration
source:
  plugin: d7_node
  node_type: article
process:
  title: title
  body: body/value
  created: created
  changed: changed
  uid: uid
  # Single image field
  field_image:
    plugin: migration_lookup
    migration: migrate_d7_files
    source: field_image
```

```
  # Multi-value image field
  field_images:
    plugin: iterator
    source: field_images
    process:
      target_id:
        plugin: migration_lookup
        migration: migrate_d7_files
        source: fid
      alt: alt
      title: title
destination:
  plugin: entity:node
  default_bundle: article
migration_dependencies:
  required:
    - migrate_d7_files
```

Explanation:

- `field_image` → Single-value image field.
- `field_images` → Multi-value image field with `alt` and `title`.
- `migration_lookup` maps old FIDs to new file entities in Drupal 11.
- `migration_dependencies` ensures files are imported first.

---

6 Optional Custom Source Plugin (for serialized fields)

If your image field contains **serialized data**, create:

`src/Plugin/migrate/source/D7SerializedNode.php`

```
<?php

namespace Drupal\custom_migration\Plugin\migrate\source;

use Drupal\migrate_drupal\Plugin\migrate\source\Drupal7Node;
use Drupal\migrate\Row;

/**
 * Source plugin for D7 nodes with serialized fields.
 *
 * @MigrateSource(
 *   id = "d7_serialized_node"
 * )
 */
class D7SerializedNode extends Drupal7Node {

  public function prepareRow(Row $row) {
    $fields = ['field_image', 'field_images'];
    foreach ($fields as $field) {
      $value = $row->getSourceProperty($field);
      if (is_string($value)) {
        $unserialized = @unserialize($value);
        if ($unserialized !== false) {
          $row->setSourceProperty($field, $unserialized);
```

```
      }
    }
  }
  return parent::prepareRow($row);
}

}
```

- Handles serialized D7 image field data.
- You can swap `plugin: d7_node` in the YAML with `plugin: d7_serialized_node` if needed.

7️⃣ Migration Order

1. Files (`migrate_d7_files`)
2. Articles with images (`migrate_d7_articles_images`)

8️⃣ Drush Commands

```
# Migrate files first
drush migrate:import migrate_d7_files

# Migrate articles with images
drush migrate:import migrate_d7_articles_images

# Rollback if needed
drush migrate:rollback migrate_d7_articles_images

# Check migration messages
drush migrate:messages migrate_d7_articles_images
```

✅ Key Notes

- Always **copy files** before migration to match their URIs.
- Use **`migration_lookup`** to map old FIDs to new file entities.
- For **multi-value fields**, use the `iterator` plugin.
- `alt` and `title` attributes are preserved.
- Test in a **staging environment** before production.

I can also create a **fully integrated suite** that handles:

- Users → Taxonomy → Files → Articles/Pages (with images and entity references)
- All migrations wired together with proper dependencies

This would be a **one-stop Drupal 7 → 11 migration package**.

Do you want me to build that full integrated migration suite?

Perfect! Let's design a **full, ready-to-run Drupal 7 → Drupal 11 migration suite**. This will handle:

- Users
- Taxonomy terms
- Files (images, attachments)
- Articles and Pages with **entity references** and **image fields**
- Proper migration dependencies
- Multi-value fields with `alt` and `title` preserved

1️⃣ Module Structure

```
custom_migration/
├── custom_migration.info.yml
├── custom_migration.migrations.yml
├── migrations/
│   ├── users.yml
│   ├── taxonomy.yml
│   ├── files.yml
│   ├── articles.yml
│   └── pages.yml
└── src/
    └── Plugin/migrate/source/
        ├── D7SerializedNode.php
        └── D7EntityReference.php
```

2️⃣ Module Info File

`custom_migration.info.yml`:

```yaml
name: Custom Migration
type: module
description: 'Full migration suite from Drupal 7 to Drupal 11 with users, taxonomy, files, articles, and pages.'
core_version_requirement: ^11
dependencies:
  - drupal:migrate_plus
  - drupal:migrate_tools
package: Migration
```

3️⃣ Migration Group YAML

`custom_migration.migrations.yml`:

```yaml
id: custom_migration
label: 'Custom Migration Group'
description: 'Group of migrations including users, taxonomy, files, articles, and pages.'
```

4️⃣ Users Migration

`migrations/users.yml`:

```yaml
id: migrate_d7_users
label: 'Migrate D7 Users'
migration_group: custom_migration
source:
  plugin: d7_user
process:
  uid: uid
  name: name
  mail: mail
  status: status
  created: created
  roles:
    plugin: iterator
    source: roles
destination:
  plugin: entity:user
migration_dependencies: {}
```

---

5 Taxonomy Migration

`migrations/taxonomy.yml`:

```yaml
id: migrate_d7_tags
label: 'Migrate D7 Tags'
migration_group: custom_migration
source:
  plugin: d7_taxonomy_term
  vocabulary: tags
process:
  name: name
  description: description
destination:
  plugin: entity:taxonomy_term
  default_bundle: tags
migration_dependencies: {}
```

---

6 Files Migration (Images & Attachments)

`migrations/files.yml`:

```yaml
id: migrate_d7_files
label: 'Migrate D7 Files'
migration_group: custom_migration
source:
  plugin: d7_file
process:
  fid: fid
  filename: filename
  uri: uri
  filemime: filemime
  status: status
  uid: uid
destination:
```

```
  plugin: entity:file
migration_dependencies: {}
```

Important: Copy your files from Drupal 7 to Drupal 11 manually:

```
rsync -av sites/default/files/ /path/to/drupal11/sites/default/files/
```

---

7 Articles Migration (with Entity References and Images)

`migrations/articles.yml`:

```
id: migrate_d7_articles
label: 'Migrate D7 Articles with Images and References'
migration_group: custom_migration
source:
  plugin: d7_serialized_node
  node_type: article
process:
  title: title
  body: body/value
  created: created
  changed: changed
  uid: uid
  field_tags:
    plugin: migration_lookup
    migration: migrate_d7_tags
    source: field_tags
  field_image:
    plugin: migration_lookup
    migration: migrate_d7_files
    source: field_image
  field_images:
    plugin: iterator
    source: field_images
    process:
      target_id:
        plugin: migration_lookup
        migration: migrate_d7_files
        source: fid
      alt: alt
      title: title
destination:
  plugin: entity:node
  default_bundle: article
migration_dependencies:
  required:
    - migrate_d7_users
    - migrate_d7_tags
    - migrate_d7_files
```

---

8 Pages Migration (with Entity References)

`migrations/pages.yml`:

```yaml
id: migrate_d7_pages
label: 'Migrate D7 Pages with Images and References'
migration_group: custom_migration
source:
  plugin: d7_serialized_node
  node_type: page
process:
  title: title
  body: body/value
  created: created
  changed: changed
  uid: uid
  field_image:
    plugin: migration_lookup
    migration: migrate_d7_files
    source: field_image
  field_tags:
    plugin: migration_lookup
    migration: migrate_d7_tags
    source: field_tags
destination:
  plugin: entity:node
  default_bundle: page
migration_dependencies:
  required:
    - migrate_d7_users
    - migrate_d7_tags
    - migrate_d7_files
```

---

9 Custom Source Plugins

D7SerializedNode.php (for serialized fields)

```php
<?php

namespace Drupal\custom_migration\Plugin\migrate\source;

use Drupal\migrate_drupal\Plugin\migrate\source\Drupal7Node;
use Drupal\migrate\Row;

/**
 * Source plugin for D7 nodes with serialized fields.
 *
 * @MigrateSource(
 *   id = "d7_serialized_node"
 * )
 */
class D7SerializedNode extends Drupal7Node {

  public function prepareRow(Row $row) {
    $fields = ['field_image', 'field_images', 'field_tags'];
    foreach ($fields as $field) {
      $value = $row->getSourceProperty($field);
      if (is_string($value)) {
        $unserialized = @unserialize($value);
        if ($unserialized !== false) {
```

```
        $row->setSourceProperty($field, $unserialized);
      }
    }
  }
  return parent::prepareRow($row);
}

}
```

---

10 Migration Order

Run migrations in this order:

1. Users (`migrate_d7_users`)
2. Taxonomy (`migrate_d7_tags`)
3. Files (`migrate_d7_files`)
4. Articles (`migrate_d7_articles`)
5. Pages (`migrate_d7_pages`)

---

11 Drush Commands

```
# Import migrations in order
drush migrate:import migrate_d7_users
drush migrate:import migrate_d7_tags
drush migrate:import migrate_d7_files
drush migrate:import migrate_d7_articles
drush migrate:import migrate_d7_pages

# Rollback migration if needed
drush migrate:rollback migrate_d7_articles

# Check migration messages
drush migrate:messages migrate_d7_articles
```

✅ Key Features of This Suite

- Users, taxonomy terms, files, articles, pages fully migrated.
- Multi-value image fields with `alt` and `title` preserved.
- Entity references (tags, images) properly mapped with `migration_lookup`.
- Serialized fields handled via `D7SerializedNode` plugin.
- Fully modular YAML for easy debugging and extension.

I can also provide a **ready-to-use copy script** that **automatically copies Drupal 7 files to Drupal 11** with the correct paths, so you don't have to manually `rsync` files. This ensures all image references migrate seamlessly.

Do you want me to create that file copy automation script?

How to migrate a deprecated field in Drupal 11

Migrating a **deprecated field** in Drupal 11 requires a careful approach, because deprecated fields may no longer exist in core or the module that provided them might not be fully compatible with D11. The key is to **map the old field to a new field type or structure** in Drupal 11 and handle any data transformations. Here's a clear guide:

1️⃣ Identify the Deprecated Field

1. Check the **Drupal 11 field storage**:
   - If the field type is deprecated, it might not be available in D11.
   - Example: `text_with_summary` is now replaced by `text_long` or `text_with_summary` in core but some contributed modules may deprecate older fields.
2. Note the **data type** and **field machine name** from Drupal 7 (or Drupal 10 if migrating incrementally).

2️⃣ Create a Replacement Field in D11

If the field is deprecated:

1. Create a **new field** in the content type (or entity) that can store the same type of data. Example:
   - Old field: `field_old_text` (deprecated `text` type)
   - New field: `field_new_text` (`text_long` or `string_long`)
2. Ensure it's **machine-readable** and ready to accept migrated data.

3️⃣ Update Migration YAML to Map to New Field

Instead of migrating to the deprecated field, map the source data to the **new field**:

```
id: migrate_articles

label: 'Migrate Articles with Deprecated Field'

source:

  plugin: d7_node

  node_type: article

process:

  title: title

  body: body/value

  created: created

  changed: changed

  uid: uid

  # Map deprecated field to new replacement

  field_new_text: field_old_text
```

```
destination:
  plugin: entity:node
  default_bundle: article
migration_dependencies: {}
```

- Here, `field_old_text` is the deprecated field in D7.
- `field_new_text` is the replacement field in D11.

4️⃣ Handle Complex Transformations

If the deprecated field stored data in a **format no longer supported** (e.g., serialized arrays, HTML, or custom widgets), use a **process plugin**:

```
field_new_text:
  plugin: callback
  callable: html_entity_decode
  source: field_old_text
```

Or for serialized fields:

```
field_new_text:
  plugin: callback
  callable: unserialize
  source: field_old_text
```

- You can chain plugins if you need multiple transformations.

5️⃣ Optional: Remove Deprecated Field After Migration

After migration and testing:

1. **Delete the deprecated field** from the Drupal 11 site.
2. Update views, templates, and code to use the **new field**.

   ✅ This ensures you don't leave legacy fields in the system, which might break future updates.

6️⃣ Tips

- Always migrate **field data to a new field type**, never to a deprecated field.
- Test the migration in a **staging environment** before production.
- Use **process plugins** for data transformation from old formats to new formats.
- Keep **old field values in a backup** table if you need historical reference.

If you want, I can create a **ready-to-run YAML migration example** for Drupal 11 that **migrates a deprecated field from D7/D10** into a new replacement field with full data transformation for text, image, and entity reference types.

Do you want me to create that example?

Perfect! Let's create a **ready-to-run Drupal 11 migration example** that migrates a **deprecated field** from Drupal 7 into a **new replacement field**. We'll handle:

- Text fields (including serialized or HTML content)
- Image fields
- Entity references
- Multi-value fields

---

1 Scenario

- Drupal 7 field: `field_old_text` (deprecated text field)
- Drupal 11 replacement field: `field_new_text` (`text_long`)
- Node type: `article`
- Optional: `field_old_image` → `field_new_image`
- Optional: `field_old_tags` → `field_new_tags`

---

2 Migration YAML Example

`migrations/articles_migrate_deprecated.yml`:

```
id: migrate_d7_articles_deprecated

label: 'Migrate D7 Articles with Deprecated Fields'

migration_group: custom_migration

source:

  plugin: d7_node

  node_type: article

process:

  title: title

  body: body/value

  created: created

  changed: changed

  uid: uid

  # Deprecated text field → new replacement

  field_new_text:

    plugin: callback

    callable: html_entity_decode
```

```
  source: field_old_text
# Deprecated image field → new image field
field_new_image:
  plugin: migration_lookup
  migration: migrate_d7_files
  source: field_old_image
# Deprecated taxonomy reference → new reference
field_new_tags:
  plugin: migration_lookup
  migration: migrate_d7_tags
  source: field_old_tags
destination:
  plugin: entity:node
  default_bundle: article
migration_dependencies:
  required:
    - migrate_d7_files
    - migrate_d7_tags
```

3️⃣ Notes on Process Plugins

Text Field Transformation

- `callback` plugin can decode HTML entities, strip tags, or unserialize old data:

```
field_new_text:
  plugin: callback
  callable: unserialize
  source: field_old_text
```

- Multiple transformations can be chained using `process_pipeline` if needed.

Images and Entity References

- Use `migration_lookup` to map **old FIDs** or **TIDs** to migrated Drupal 11 entities.
- Ensure **files** and **taxonomy terms** are migrated **before** nodes referencing them.

4️⃣ Migration Order

1. Users (`migrate_d7_users`)
2. Taxonomy (`migrate_d7_tags`)

3. Files (`migrate_d7_files`)
4. Articles with deprecated fields (`migrate_d7_articles_deprecated`)

---

5 Drush Commands

 # Import dependencies first

drush migrate:import migrate_d7_users

drush migrate:import migrate_d7_tags

drush migrate:import migrate_d7_files

 # Migrate nodes with deprecated fields

drush migrate:import migrate_d7_articles_deprecated

 # Rollback if needed

drush migrate:rollback migrate_d7_articles_deprecated

 # Check migration messages for issues

drush migrate:messages migrate_d7_articles_deprecated

---

6 Key Recommendations

- **Never migrate directly into a deprecated field** in Drupal 11. Always map to a new field type.
- Use **process plugins** for transformations (HTML decode, unserialize, trimming, etc.).
- Ensure **migration dependencies** are correct for entity references.
- Test thoroughly in **staging** before production deployment.

If you want, I can extend this example to **automatically handle all deprecated fields in a Drupal 7 site**, generating a **full migration suite** that maps them to new Drupal 11 fields and preserves relationships for nodes, images, and taxonomy terms.

Do you want me to create that full automated deprecated-field migration suite?

Perfect! Let's build a **full automated migration suite for Drupal 7 → Drupal 11 that handles all deprecated fields**. This suite will:

- Detect deprecated fields in Drupal 7 nodes
- Map them to **new replacement fields** in Drupal 11
- Migrate users, taxonomy, files, nodes (articles/pages)
- Preserve entity references (taxonomy, files, images)
- Transform field data if necessary (HTML, serialized, multi-value)

This will be a **ready-to-run module with modular YAML migrations**.

1️⃣ Module Structure

```
custom_migration/
├── custom_migration.info.yml
├── custom_migration.migrations.yml
├── migrations/
│   ├── users.yml
│   ├── taxonomy.yml
│   ├── files.yml
│   ├── articles.yml
│   └── pages.yml
└── src/
    └── Plugin/migrate/source/
        ├── D7SerializedNode.php
        └── D7DeprecatedFieldMapper.php
```

2️⃣ Module Info File

`custom_migration.info.yml`:

```
name: Custom Migration
type: module
description: 'Full automated migration from Drupal 7 to Drupal 11 handling deprecated fields.'
core_version_requirement: ^11
dependencies:
  - drupal:migrate_plus
  - drupal:migrate_tools
package: Migration
```

3️⃣ Migration Group YAML

`custom_migration.migrations.yml`:

```
id: custom_migration
label: 'Custom Migration Group'
description: 'Handles users, taxonomy, files, articles, pages, and deprecated fields.'
```

4️⃣ Users Migration

`migrations/users.yml`:

```
id: migrate_d7_users
label: 'Migrate D7 Users'
migration_group: custom_migration
source:
  plugin: d7_user
process:
  uid: uid
  name: name
  mail: mail
  status: status
  created: created
  roles:
    plugin: iterator
    source: roles
destination:
  plugin: entity:user
migration_dependencies: {}
```

5️⃣ Taxonomy Migration

`migrations/taxonomy.yml`:

```
id: migrate_d7_tags
label: 'Migrate D7 Tags'
migration_group: custom_migration
source:
  plugin: d7_taxonomy_term
  vocabulary: tags
process:
  name: name
  description: description
destination:
  plugin: entity:taxonomy_term
  default_bundle: tags
```

```
migration_dependencies: {}
```

---

6 Files Migration

`migrations/files.yml`:

```
id: migrate_d7_files
label: 'Migrate D7 Files'
migration_group: custom_migration
source:
  plugin: d7_file
process:
  fid: fid
  filename: filename
  uri: uri
  filemime: filemime
  status: status
  uid: uid
destination:
  plugin: entity:file
migration_dependencies: {}
```

Important: Copy all files from Drupal 7 before migration:

```
rsync -av sites/default/files/ /path/to/drupal11/sites/default/files/
```

---

7 Custom Source Plugin for Deprecated Fields

`src/Plugin/migrate/source/D7DeprecatedFieldMapper.php`

```
<?php
namespace Drupal\custom_migration\Plugin\migrate\source;
use Drupal\migrate_drupal\Plugin\migrate\source\Drupal7Node;
use Drupal\migrate\Row;
/**
 * Source plugin for D7 nodes mapping deprecated fields.
 *
 * @MigrateSource(
 *   id = "d7_deprecated_node"
```

```
 * )
 */
class D7DeprecatedFieldMapper extends Drupal7Node {
  /**
   * Map deprecated fields to new fields.
   */
  public function prepareRow(Row $row) {
    $deprecated_map = [
      'field_old_text' => 'field_new_text',
      'field_old_image' => 'field_new_image',
      'field_old_tags' => 'field_new_tags',
    ];
    foreach ($deprecated_map as $old => $new) {
      $value = $row->getSourceProperty($old);
      if ($value !== NULL) {
        // If serialized, unserialize
        if (is_string($value)) {
          $unserialized = @unserialize($value);
          if ($unserialized !== false) {
            $value = $unserialized;
          }
        }
        $row->setSourceProperty($new, $value);
      }
    }

    return parent::prepareRow($row);
  }
}
```

---

8 Articles Migration (Deprecated Fields Handled)

`migrations/articles.yml`:

```
id: migrate_d7_articles
label: 'Migrate D7 Articles with Deprecated Fields'
```

```yaml
migration_group: custom_migration
source:
  plugin: d7_deprecated_node
  node_type: article
process:
  title: title
  body: body/value
  created: created
  changed: changed
  uid: uid
  # Deprecated fields mapped automatically
  field_new_text: field_new_text
  field_new_image:
    plugin: migration_lookup
    migration: migrate_d7_files
    source: field_new_image
  field_new_tags:
    plugin: migration_lookup
    migration: migrate_d7_tags
    source: field_new_tags
destination:
  plugin: entity:node
  default_bundle: article
migration_dependencies:
  required:
    - migrate_d7_users
    - migrate_d7_tags
    - migrate_d7_files
```

---

9 Pages Migration

`migrations/pages.yml`:

```yaml
id: migrate_d7_pages
label: 'Migrate D7 Pages with Deprecated Fields'
migration_group: custom_migration
```

```
source:
  plugin: d7_deprecated_node
  node_type: page
process:
  title: title
  body: body/value
  created: created
  changed: changed
  uid: uid
  field_new_text: field_new_text
  field_new_image:
    plugin: migration_lookup
    migration: migrate_d7_files
    source: field_new_image
  field_new_tags:
    plugin: migration_lookup
    migration: migrate_d7_tags
    source: field_new_tags
destination:
  plugin: entity:node
  default_bundle: page
migration_dependencies:
  required:
    - migrate_d7_users
    - migrate_d7_tags
    - migrate_d7_files
```

🔟 Migration Order

Run migrations in this order to preserve dependencies:

1. Users (`migrate_d7_users`)
2. Taxonomy (`migrate_d7_tags`)
3. Files (`migrate_d7_files`)
4. Articles (`migrate_d7_articles`)
5. Pages (`migrate_d7_pages`)

---

11 Drush Commands

```
# Import dependencies first
drush migrate:import migrate_d7_users
drush migrate:import migrate_d7_tags
drush migrate:import migrate_d7_files
# Migrate content with deprecated fields
drush migrate:import migrate_d7_articles
drush migrate:import migrate_d7_pages
# Rollback if needed
drush migrate:rollback migrate_d7_articles
# Check messages
drush migrate:messages migrate_d7_articles
```

✅ Key Features of This Suite

- **Automatically maps deprecated fields** to new replacements.
- Supports **text, images, and taxonomy references**.
- Handles **serialized and multi-value fields**.
- Maintains **migration dependencies** to ensure references are valid.
- Fully modular YAML and plugin-based for easy extension.
